Introduction

The purpose of this study was to introduce hydrogel material for development of tissue-engineered full-thickness artificial skin using visible light-curable gelatin with autologous dermal fibroblasts and epidermal keratinocyte for treating wounds.

Materials and Methods

Cultured autologous fibroblasts were seeded on the visible light-curable gelatin and gelatinization was occurred. After fibroblast gelatinization, cultured autologous keratinocytes were seeded on the layer of fibroblasts to create full-thickness artificial skin.

To create tissue-engineered full-thickness artificial skin using visible light-curable gelatin with autologous dermal fibroblasts and epidermal keratinocytes, we need to develop the hydrogel using gelatin/ABS (azido benzoyloxy succinimide) and FITC-BSA using confocal dish.

Results

First of all, our group produced and synthesized ABS structures as following methods. After synthesis of ABS structure, we produced hydrogel type for visible light-curable gelatin for cell-seeding scaffold to create the tissue-engineered full-thickness artificial skin.

Production of ABS(Azido Benzoyloxy Succinimide)

Synthesis of ABS structure

Porcine Gelatin(2.001g)

- ← H₂O 180ml
- ← Adjust pH 11 with dil-NaOH
- ← Ice Bath
- ← ABS (Azidobenzoyloxy succinimide) 1.701g
- ← Appropriate amount of 1,4-Dioxane(15ml)
- ← After natural heating, 50°C, 24hr reaction
- ← White precipitate
- ← Evaporation
- ← Dioxan, Acetone, D.E washing

Hydrogel for visible light-curable gelatin

Conclusion

Tissue-engineered full-thickness artificial skin using visible light-curable autologous dermal fibroblasts and epidermal keratinocytes may be an effective and safe for treatment of wounds. We look forward to create the gelatin for tissue-engineered full-thickness artificial skin and larger pivotal in vivo studies to confirm these initially promising findings.
